Recent database systems have built systematic data analysis capabilities on database data using data warehousing and data mining facilities. A data warehouse integrates data originating from multiple sources and various timeframes. It consolidates data in multidimensional space to form partially materialized data cubes. 1 Introduction. Database systems have exploited parallelism from the very beginning (in the early 60s), in a way similar to operating systems. An operating system allows many users to use the same hardware concurrently, i.e. in parallel, and a database system allows the same database to be concurrently accessed by many application programs. Data warehouses typically range in size from tens of gigabytes to a few terabytes, usually with the vast majority of the data stored in a few very large fact tables. OLTP vs OLAP examples. OLAP tends to conduct more aggregated actions across a large amount of data (i.e. sum of sales for region X). We can also have OLAP schemas Take data from operational systems -> Integrate the data from multiple sources -> Standardize the data & remove inconsistencies -> Store the data in a format suitable for easy access & analysis on any time axis from integrated sources. Example DWH Architecture / Process Flow. More detailed DWH process. Understanding databases and DWH is crucial for data scientists today in the age of "big data". Austen Myers.
